STUTT GART, ARK.

A disease that can prevent rice grains from filling out has been confirmed in a field in western Greene Co., prompting a warning to scout late rice fields. The warning is for "late-planted fields with blast-susceptible varieties in blast-prone areas," said Yeshe Wamishe, extension plant pathologist.

"If you have rice fields at booting to early heading, the crop could still benefit from a fungicide application," she said. "Timing is important. Once the head is completely out of the boot, a fungicide application has no benefit for prevention of neck or panicle blast."
